

A. Split the channels; each group covers the whole image

Channel values shown in grayscale: black = 0, white = 1. Alpha is a data channel.

B. One block: keep u available to reproduce the adjustment

FORWARD

Keep $u' = u$; compute $t = t_\theta(u, n)$.

$$v \longrightarrow 0.5v + t = v'$$

Example: $0.5 \times 0.8 + 0.3 = 0.7$

REVERSE

Keep $u = u'$; recompute $t = t_\theta(u', n)$.

$$v' \longrightarrow (v' - t)/0.5 = v$$

Undo: $(0.7 - 0.3)/0.5 = 0.8$

Same network + unchanged group + same saved noise = same adjustment.

C. Alternate groups across the four network blocks
